DEAD LEAVES, SKY FRAGMENTS and SNOW BUTTERFLIES

Article and Photos by Carroll Rudy

It's one of those enchanting early spring days. The sun is bright and warm, the sky is blue, and the woods invite you to explore. Here and there a crusty remnant of last winter's snow melts into the spongy ground, the trees are still bare and there is not a flower in sight.

As you hike along the trail, last year's dead leaves crackle beneath your feet, when suddenly one of the "dead leaves" explodes into flight—it's a butterfly! At rest, the outside of the folded wings looked just like old dried leaves, but in flight the bright orange and russet inside colors flash in the sun. The butterfly is fast—very fast! Your eyes cannot follow it or see its markings, and it defies any hungry bird or curious person to even get close.

Where did this butterfly come from so long before any flowers bloom, while blizzards still threaten and the trees are bare. What does it eat?

This butterfly is one of many species that hibernate right through the coldest winters and can be seen flying about anytime the temperatures near the 60 degree mark; even in midwinter. Often called Angle Wings, these hibernators have angular, notched wings as if they were snipped with scissors into the shape of old leaves, and the outside surfaces are drab and crusty-looking

Mourning Cloak Butterfly

Question Mark Butterfly

like gray tree bark. The camouflage helps to hide them while they hibernate.

Two Angle Wings frequently seen are the Question Mark and the Comma—two similar species that bear silver marks on their hind wings that resemble punctuation marks. Other hibernators you can find in winter are several species of Tortoiseshell Butterflies

and the Mourning Cloak. Tortoiseshells are similar to Angle Wings but lack the silver punctuation marks. Mourning Cloaks, however are the most conspicuous early spring butterfly of all because they are the largest (3 in.). In flight, the deep maroon wings appear black with cream edges all around and bear bright blue spots. Of course you'll be lucky if you see those beautiful markings because the butterfly is so fast.

The Wisconsin Entomological Society Newsletter is published three times a year, at irregular intervals. It is provided to encourage and facilitate the exchange of information by the membership, and to keep the members informed of the activities of the organization. Members are strongly encouraged to contribute items for inclusion in the newsletter. Please send all news items, notes, new or interesting insect records, season summaries, and research requests to the editor:

Janice Stiefel, 2125 Grove Road, Bailey's Harbor, WI 54202, (920) 839-9796, e-mail: jstiefel@itol.com

NOTE: Please report any address changes to Les Ferge, 7119 Hubbard Ave., Middleton, WI 53562. e-mail: ferge@chorus.net

INSECT BOOKS AND WEBSITES

Submitted by Andrew Khitsun

A book recently became available on *Grasshoppers, Katydid & Crickets of the United States* by J. Capinera and others. It covers about one-third of all North American species.

An interesting set of books exist for those of you living or traveling up North frequently, the North Woods Naturalist series. I found several: *Butterflies of the North Woods*, *Butterflies of New England*, *Spiders of the North Woods* by L. Weber; *Dragonflies of the North Woods* by K. Mead; *Damselflies of the North Woods* by WES member, Robert DuBous (with photos by WES member Mike Reese).

The ever expanding series *Moths of America North of Mexico*, currently sports 24 volumes, of which 14 are devoted to micromoths (Pyralidae, Gelechiidae, Oecophoridae, Cosmopterigidae, and Sesidae). One treats Geometridae; two books cover Saturniidae and one covers three related families (Apateleodidae, Bombycidae and Lasiocampidae). Sphingidae and Lymantridae each have their own volume. Noctuidae are dealt with in four books.

For those interested in moths I'd like to suggest some websites. *Microlepidoptera of Finland* deals in detail with a wide variety of moths of that group in Northern Europe at <http://klmmos.freeshell.org/micro/>

Moth Photographers Group at <http://mothphotographersgroup.msstate.edu/MainMenu.shtml> has a wide array of photos of almost two thousand species from a number of people, including WES members. This site includes photos of living moths, as well as pinned specimens.

Moth images on the Web compiles images of thousands of North American species from a number of sites and authors at <http://facweb.furman.edu/~snyder/ohn/leplist/>

BugGuide features a large number of various families of insects, spiders and their kin. It includes data on where and when each insect was found. There is space for making comments or asking questions about the photos that are posted. Some WES members' photos are also posted on this website:

<http://bugguide.net>

Submitted by Dreux Watermolen

The Wisconsin Department of Natural Resources recently published a *Guide to the Grasshoppers of Wisconsin*. This 150-page book, written by Kathryn Kirk of the DNR's Bureau of Endangered Resources and UW-Stout biology professor, Charles R. Bomar, and edited by WES member Dreux Watermolen, provides the first comprehensive up-to-date reference available for grasshopper species occurring in Wisconsin. The spiral bound guide includes keys for identification, full color plates, maps of known species distributions, descriptions of habitat, and comments on the status, life history, and ecology of individual species. *Guide to the Grasshoppers of Wisconsin* is available free of charge from the Bureau of Integrated Science Services. To obtain copies, contact Martin Griffin, Science Communications Manager, at (608)-266-0842 or Martin.Griffin@dnr.state.wi.us. For information on how to order hard copies of the book online or to view and download the guide electronically, please visit:

Answer to October 2005 MYSTERY INSECT

**Boxwood Leaflier
Moth**

(*Galasa nigrinodis*)
Photo: Carroll Rudy

It seems that the Mystery Insect for October stumped many people. There was one answer and it was correct. It came from Ron Huber of Bloomington, MN. He said,

"It looks like a pyralid moth, sub-family Chrysauginae, and matches nicely with *Galasa nigrinodis*, shown on Plate 59 in Covell's Field guide." 🌿

DID YOU KNOW?

...that you could spell the word "butterfly" with butterflies? Or you could spell your own name with butterflies? You could even write the year of your birth with butterflies. And if you had enough different butterflies, you could even include the month and day you were born.

Nature photographer, Kjell Sandved, has assembled a most unusual and amazing butterfly and moth collection. Traveling all over the world, he has photographed the wings of many of the world's 200,000 butterfly and moth species. The project began more than 30 years ago when he saw a butterfly wing with a perfect representation of the letter "F." Since then Sandved has photographed several representations of every letter of the English alphabet, all the arabic numerals and many non-English letters on the wings of butterflies and moths. He has also found images of plants and animals as well as human faces on the wings of these insects.

Some of the markings on butterflies and moths are part of their camouflage. In other cases, like the giant eyespot on each wing of some butterflies and moths, the spot is known to keep birds away...beauty and protection with a little bit of mystery and intrigue thrown in. 🌿

Snow Butterflies from Page 1

All of these butterflies flit about the leafless woods looking for sweet sap that has oozed from wounded trees. Sap serves as their food in the spring while in autumn they favor rotting fruit along with an occasional treat of animal dung for variety. Apparently they find their food

Comma Butterfly

by its odor. Butterflies hibernate in hollow trees, under loose bark, in unheated buildings, crevices in the rocks, bird houses, tin cans...any place protected from wind and wet. Unfortunately most are discovered by mice or birds and devoured. You can build a hibernation box to help them out and keep the predators away from them.

Another very early April butterfly to watch for is the Spring Azure which sometimes emerges from its pupa before all the snow is gone. Most people never notice them because they are so tiny—less than an inch across. In spite of their small size, they are one of the most beautifully colored of all our butterflies, looking like tiny fragments of bright blue sky fluttering about spring mud puddles where they dine daintily upon bird droppings and other tasty fare. While resting on the mud, they are inconspicuous since their closed wings match the mud in color.

Need A Project Chasing Bumblebees?

by Andrew Williams

Recently, I took a call from Liz Day, who asked if I had collected *Bombus affinis* or *B. terricola* in the last few years. I had not. Actually, I've no research under way that causes me to collect bees. Liz thinks these two native bees are vanishing, or have vanished, from large parts of their ranges in just a couple years. Have you recently collected either of these bees?

This could be a great opportunity to pursue in the next field season. Bumblebees are large and relatively easy to determine, and this could be a fine project to introduce children to insect collection, conservation, curation, etc. Liz reminded me that these two species show some rusty fuzz as well as yellow fuzz on their abdomens, which makes them very recognizable in the field. She assured me she would help anyone interested in this project with keys to quickly determine bees in the field.

Back in 1963, J. T. Medler and D. W. Carney published *Bumblebees of Wisconsin (Hymenoptera: Aptidae)* as Research Bulletin 240 of the UW-Madison Agricultural Experiment Station. From this, I learned that *B. affinis* occurs statewide in Wisconsin, but is hard to find in the north, and that it commonly lives in urban environments, nesting in subterranean spaces in the rubble fill beside the concrete walls of houses. *Bombus terricola* is widespread in the north and absent from southwestern Wisconsin. It has been collected as far south as Dane County and in southeastern Wisconsin counties. If any of you have data to share with Liz, or would like her help getting organized to pursue these bumblebees over next field season, or even to be casually looking for these particular species when you see bumblebees on flowers, please contact Liz at beebuzz@kiva.net or at 317-924-0008.

In mid-April when the snowy hedgerows of wild plum begin to bloom, more butterflies suddenly appear. They are less hardy species which have flown in from the south where they hibernated through a milder winter than ours. Sometimes they migrate in large flocks; other times they are scarce. Most of them are Red Admirals or Painted Ladies, and they are very colorful among the white plum blossoms. Remember that 10 in. blizzard we had in the May of 1990? The butterflies had already arrived in large flocks and some survived the blizzard.

So when you get spring fever and take those spring hikes in the woods, watch for early butterflies. Why not take along a butterfly guide as well as your bird guide. It will open up an entire new world of wildlife observation for you.

Carroll is a WES member from Calumet County. She is a former biology teacher and is currently editor of Chilton's Ledge View Nature Center Newsletter.

MYSTERY INSECT

Can you identify it?

Densely covered with gray pubescence, variegated with patches of yellow hairs on elytra and on head; pronotum has three yellow stripes; front of head and scutellum yellow; underneath gray, with yellow patches. Body about 7/8 in. Send answer to the editor. Winners will be announced in the next newsletter.

KYLE JOHNSON

Detailed close-up of one of Anita's beetles.

WES ANNUAL MEETING

The Wisconsin Entomological Society's Annual Meeting and Photo Salon was held October 15, 2005 in Madison at Russell Labs on the UW-Madison campus. It was attended by about 30 people. A brief business meeting was called to order by President, Megan Hyslop. The existing officers (except the president, who asked to step down), agreed to serve for another term. Andrew Williams received a unanimous vote to serve as president.

A slide program of rare Wisconsin peatland Lepidoptera was presented by Kyle Johnson. We were impressed by his photos and the amount of research he has done on this subject. The annual Photo Salon was a treat, as usual. Winners have been previously announced under each photo shown on pages 4 and 5.

WES member, Anita Carpenter, shared a spectacular handmade quilt of Wisconsin beetles. The black and white photos below do not do it justice. Anita worked on this quilt for over a year...who knows how many hours? She could have sold one to everyone in attendance. Members brought photos and specimens for ID. We had a great time discussing observations and summer's experiences. 🌿

2005 WISCONSIN LEPIDOPTERA SEASON SUMMARY

Coordinator: Leslie A. Ferge

**CONTRIBUTORS CITED: James A. Ebner (JAE), Leslie A. Ferge (LAF),
Kyle E. Johnson (KEJ), Janice J. Stiefel (JJS), Ann and Scot Swengel (SAS)**

Spring weather conditions were erratic, with April being unseasonably warm and May being chilly and rainy, with few suitable days for field work. Summer was hot, with near drought conditions prevalent. Late season was relatively mild, with no significant freezes holding off well into October. Numbers of many usually common butterfly species continue to be depressed in localities where they formerly were plentiful. However, *Papilio glaucus* and *P. canadensis* were found in good numbers. The bog-inhabiting *Boloria* species also had a good season, with several new county records reported. It was not a good year for migrants, with the relatively few species noted generally found as single individuals or in small numbers. Monarch numbers remained low throughout the season.

New County and State Records are indicated in CAPITAL letters

New Species of Dragonfly Discovered in Wisconsin

submitted by Dreux Watermolen

MADISON — From *DNR News*

Six years after the original specimen was collected along the banks of Wisconsin's Eau Claire River, the scientific community has officially recognized a new species of dragonfly discovered by a state Department of Natural Resources biologist. A medium-sized insect with an impressive name, *Ophlogomphus smithi* (pronounced smith-eye), is named after its discoverer, William Smith, a biologist with the DNR Bureau of Endangered Resources.

Originally thought to be an example of an already-named dragonfly species, the determination of *O. smithi* as a distinct species was confirmed when two other entomologists in the mid 1990s recognized important differences in the specimen collected by Smith in Eau Claire County in 1989. The 1.8-inch dragonfly also goes by the common name of Sand Snaketall.

This is the second new dragonfly species discovered by Smith who collected an undecided species in the St. Croix River in 1989. The 1989 find was eventually named *Ophlogomphus susbehcha* in 1993 with a common name of Saint Croix Snaketall. "Susbehcha" is Lakota for dragonfly. For more information, contact Bill Smith at (608) 266-0924. ☘
