Milwaukee Public Museum Hosts Butterflies ALIVE Exhibit

ear bright clothing. Speak in whispers.

Stand as still as you can. And then—enjoy the magic. Live butterflies have returned to the Milwaukee Public Museum.

"The Puelicher Foundation presents Butterflies ALIVE!" opened July 10 and runs through Jan. 2, 2000 in the Museum's second floor Steigleder Special Exhibits Gallery. Created by Museum staff, the exhibit debuted in 1997, attracting an unprecedented number

of visitors during its five-month run.

People of all ages are awed as they stand amidst hundreds of live butterflies flying freely in the exhibit's 1,000-square-foot garden, complete with flowering plants and a waterfall. This environment offers the opportunity for visitors to see butterflies sip nectar from plants and lay eggs. Twenty-five species of butterflies native to Wisconsin and North America are featured. Two transformation stations in the garden allow visitors to see butterflies emerge from the chrysalis right before their eyes.

The butterfly garden offers a tranquil setting with a circular path around a colorful flowerbed and

waterfall where hundreds of butterflies fly freely. Many of the butterflies will land on the heads, shoulders, arms, and backs of visitors. That "personal" butterfly experience generates great enthusiasm, according to Susan Borkin, curator of Lepidoptera and project coordinator of the exhibit.

"These delicate insects, all weighing less than 1/50th of an ounce, clearly take the spotlight and create the magical atmosphere," Borkin said. "Adults and children will stand with outstretched arms, hoping to entice a

butterfly to land on them. That experience for many is the highlight of the visit."

The visitor's "personal" butterfly experience is intended to serve as the catalyst to learn more about butterflies and moths, according to Borkin. Eight educational stations, designed with colorful graphics and easy-to-read interpretive text panels, circle the rest of the 7,000-squarefoot gallery.

Visitors will learn that butterflies taste with their feet and that a butterfly's skeleton is on the outside of its body. Hands-on interactive stations outline the

WES Annual Meeting to be held at the Milwaukee Public Museum

November 1999

The next meeting of the Wisconsin Entomological Society will be held on Saturday, Nov. 13, 1999 at the Milwaukee Public Museum (map and directions appear on page 8). The meeting will begin at 1:30 P.M., in the ground floor Education Lab (signs will be posted). WES members will need to register at the Security Desk before proceeding to the lab.

The main focus of this meeting will be a guided tour through the Butterflies ALIVE Exhibit. The program will also feature our annual photo salon. Any members having slides of entomological subjects are encouraged to participate. Each entrant may submit up to five slides, labeled with the subject and name of photographer. The slides will be evaluated by the audience, which will vote to select the winning entries. The winner's name will be added to the William E. Sieker Memorial Plaque, and a print of the first place slide is added to the display in the Entomology Department office, and is also awarded to the photographer. Short presentations are scheduled.

Also on the agenda is the election of officers for 2000. Nominations are welcome, and can be made at the meeting. \Im

The Wisconsin Entomological Society Newsletter is published three times a year, at irregular intervals. It is provided to encourage and facilitate the exchange of information by the membership, and to keep the members informed of the activities of the organization. Members are strongly encouraged to contribute items for inclusion in the newsletter. Please send all news items, notes, new or interesting insect records, season summaries, and research requests to the editor:

Janice Stiefel, W6311 Mullet Lane, Plymouth, WI 53073. e-mail: jstiefel@excel.net

NOTE: Please report any address changes to Les Ferge, 7119 Hubbard Ave., Middleton, WI 53562. e-mail: ferge@chorus.net

Wisconsin Entomological Society Newsletter — November 1999

BUTTERFLIES, from Page 1

difference between butterflies and moths and help visitors better understand the impact these animals have on biological diversity. For example, learn that 50 to 90% of a butterfly or moth's offspring will not survive to become adults. Instead, they will become an integral part of the food web, fueling many other species's survival.

The return of "Butterflies ALIVE!" provides the Museum staff the opportunity to build on the earlier success of the exhibit in preparation for the Museum's permanent butterfly wing, scheduled to open in spring of 2000. William Movnihan, president of the Museum stated, "The exhibit is intended to educate and increase sensitivity to the natural world we live in." &

1999 Dues Notice

Several of our members are past due in their annual dues payment for membership in WES. To determine your status, please check the address label on this newsletter. Appearing after your name will be the last year dues were paid and your membership category:

Individual (\$5/yr.), Family (\$10/yr.), Sustaining (\$15/yr.), or Patron (\$25/vr.)

Dues are to be sent to treasurer, Tom Rocheleau, 3100 Buena Vista St., Madison, WI 53704. Be sure to notify us of any address changes or corrections. ම

Butterfly sketches on Pages 1 and 5 are by artist and naturalist. Therese Randall of Greenbush, WI.

Request for Information: Crickets, Katydids and Cicadas by Karl Legler

I am gathering information on the distribution and abundance in Wisconsin of various

Male Tree Cricket

species of Crickets, Katydids and Cicadas. 1 would like to hear from anyone who has a private collection (or observational records) that contain any of the species listed below. I am interested in the

Female Tree

Cricket

COUNTY where the species was collected (or observed) and, if possible, the date of collection. I am also interested in corresponding with anyone who is especially interested in these three groups of insects.

Bush Katydids (PHANEROPTERINAE): AMBLYCORYPHA oblongifolia, rotundifolia; MICROCENTRUM rhombifolium; SCUDDERIA curvicauda, septentrionalis, texensis.

Cone-headed Katykids (COPIPHORINAE): NEOCONOCEPHALUS robustus, lyristes.

Meadow Katydids (CONOCEPHALINAE): ORCHELIMUM campestre, concinnum, delicatum, nigripes, volantum; CONOCEPHALUS attenuatus, nemoralis, strictus.

Northern True Katydid: PTEROPHYLLA camellifolia. Field Crickets (GRYLLINAE): GRYLLUS pennsylvanicus, veletis. Ground Crickets (NEMOBIINAE): ALLONEMOBIUS allardi, griseur, maculatus; NEONEMOBIUS palustris.

Tree Crickets (OECANTHINAE); OECANTHUS niveus, quadripunctatus, argentinus.

Bush Crickets (TRIGONIDIINAE): ANAXIPHA exigua. Cicadas (HOMOPTERA: CICADIDAE): ALL cicadas (except **TIBICEN** canicularis).

> Karl Legler, 429 Franklin St., Sauk City, WI 53583 Phone: (608) 643-4926 e-mail: karlndot@bankpds.com Photos: Janice Stiefel, Sheboygan County, WI (9/13/94)

I read the June WES Newsletter from cover to cover and delight in its crisp new format. There's even a quotation from H.D. Thoreau which, like so much of his writing, is perfectly apropos today. I'm also motivated to write by the two articles concerning the Multi-colored Asian Lady Beetle. Both Phil Pellitteri and you wrote that this animal is harmless. I disagree: I believe it is harmful hereabouts. This species is not native to eastern North America. though many other species of lady beetles are native here. This species feeds on aphids and scale insects, many of which are native here. Given the astonishing abundance of the Multi-colored Asian Lady Beetle, it seems probable that some native aphid or scale species may disappear, that some parasitoids using these aphids or scale species may disappear, and that some native lady beetles that would have fed upon these aphids and scales may also disappear. Locally, our ecosystems are already burdened with the common Seven-spotted Lady Beetle, another large alien predator.

Both of these alien species were introduced by economic entomologists, who generally fail to look beyond the immediate shortterm affects to their target crop pest. I think the time has come to value the conservation of biodiversity of native organisms much more highly than we have in the past.

To paraphrase your H.D. Thoreau quotation: "These native species, living here in concert, present the greatest of God's gifts seen from this vantage point, and the influence of introduced alien taxa is usually caustic. Though God may have pronounced His work good, we are shamelessly dismantling it as we homogenize Earth's fauna and flora."

Sincerely, Andrew H. Williams Fellow in the Entomology Dept. University of Wisconsin-Madison

Wisconsin Entomological Society Newsletter --- November 1999

t was a very warm, sunny day and my job was to send the rocks I had just washed, along with mortar, up to my husband who was positioned on the roof of our Door County building project. He was constructing the masonry on the final 5 ft. of the outside wall on our fieldstone fireplace. This was not the most exciting job I've had in my life-but that was about to change...

We have observed that butterflies like wet rocks and are drawn to them like magnets. Obviously, they are seeking the minerals and moisture that the rocks contain. We've had White Admirals, Red Admirals, Mourning Cloaks, Pearl Crescents, Meadow Fritillaries, Great Spangled Fritillaries, Gray Commas, Question Marks, and occasionally a Monarch, visit our wet rock pile. We don't need a butterfly garden, we have rocks! On the 18th of September (1998), around 1 o'clock in the afternoon, an unusual, striking butterfly was fluttering around the rock pile. It didn't match any of the pictures in my butterfly books but it came closest to the description of a Common Buckeye-shades of tan, prominent eye spot along the margin of both forewing and hindwing, and two orange bars (outlined in black lines) at the top edge of the forewing. It lacked the bright cream patches on the forewing that are shown in most butterfly books. On this one the patches were quite subdued and almost unnoticeable. The Common Buckeye is migratory and somewhat rare in our part of the country, being much more prevalent in the southern states and the tropics. When it does

... To continue... this butterfly took a position on one of the rocks and just sat there. Within a few minutes another butterfly appeared, very similar, with bright cream patches on its forewing (matching the description of the Buckeye in my books), then another one arrived, and another. Now there were three Buckeyes with bright cream patches and one without the cream. It was quite obvious that the one without the cream patches was the female and the other three were males. The three males positioned themselves in equal distances from the female (about 6 in.). As soon as one tried to get closer to her, the other two would attack him and the three males would fly off in a "dog fight" to settle their dispute in the air. In a few seconds they would be back, completely encircling her again, at equal distances. This courtship went on for three hours. All she ever did was flick her wings slightly, which sent the males into a frenzy, but she did not move from her position during all that time. The guys were continually fighting or encircling her. Finally at 4 o'clock, with no mating

Male Common Buckeye (9/18/98)

Photo: Janice Stiefel

my mother told me many years ago. She had a girl friend who was so beautiful that the guys went crazy over her. They fought over her continuously, so much so that she never had one real boyfriend. This went on for several years, until she was so disgusted with men that she wanted nothing to do with them. Ultimately, she never married. I remembered this true story, when the female Buckeye flew away, leaving the males to fight among themselves.

During this three-hour courtship, my husband was patiently waiting for me to send rocks and mortar up to him on the roof. I did manage to sneak these materials to him by a much longer route-around the butterflies. It's fortunate that my labor comes cheap, because he certainly had grounds to fire me for lack of attention to my work, incompetence, and just laying down on the job. 🏈

What

was

As

T

I thought I would tell you about a web site that may be worthy of the WES's attention. The web site address is:

http://www.learner.org/jnorth This is my favorite web site because I've been following it all spring. It is an organization that tracks the migration of the Monarch Butterflies as they move north (and south) each season. It is updated each week as they are migrating. This site also tracks hummingbirds, robins, whales, etc. I hope the Wisconsin Entomological Society enjoys this fun technological wonder. 👻

For inclusion in the next BUG BYTES column, please send field observations or notes to the editor.

Wisconsin Entomological Society Newsletter — November 1999

Controlling

Earwigs Phil Pellitteri

arwigs have large, pincerslike protrusions at the rear of the body, which give them an evil appearance, but they don't harm people directly. Still, they can cause people problems by feeding on flowers and vegetables outdoors, by crawling into the home, and by congregating under well caps.

The first American report of a European Earwig (Forficula auricularia) came from Newport, Rhode Island in 1901. Until 1982 European Earwig reports in Wisconsin were limited to the Lake Michigan shoreline.

But in the years since, earwig infestations have spread fast across Wisconsin. The name "earwig" derives from a false European superstition according to which these insects enter the ears of sleeping people and bore into the brain. In fact, earwigs rarely bite—usually when sat upon or handled—and their bite is only mildly painful.

Identification and Life Cycle

Adult European Earwigs are reddish brown and about ³/₄ inch long. Their most distinctive feature is the prominent, pincers-like cerci (pronounced "sir-see") on the end of the abdomen. Earwigs use their cerci for defense, capturing prey, and sensing the environment. The cerci can pinch you if you stick a finger between them, but they can't break the skin. Male earwigs have curved cerci that are thicker at the base, while females have thin, straight cerci. In Wisconsin, pairs of earwigs overwinter by digging 2-3 inches into the soil to hibernate. Sometime during the winter or early spring the female lays 25-30 eggs. Males leave the hibernation sites first, and the females follow in late May. You may see your first earwig of the summer by mid-June. In some parts of the country the females enter the soil again to deposit a second set of eggs, but Wisconsin earwigs most likely produce just one generation per

year. Unusually wet springs and summers often intensify earwig infestations.

Earwigs eat an omnivorous diet of other insects and plants. This diet can be beneficial: earwigs feed on aphids, mites, fleas, and insect eggs. Unfortunately, in gardens they munch on dahlias, marigolds, lettuce, potatoes, and hostas. They will also feed on mosses, lichens, and algae. Earwigs are active at night and hide during the day in almost any dark, confined space, particularly if it is moist.

Female earwigs exhibit an instinct that is very rare among insects: they care for eggs and young. The females turn, lick, and reposition their eggs. They also bring food to the newly hatched young and protect them in the nest. It takes about 2 months for nymphs to mature. Earwigs' nocturnal activity, quick movements, size, and color often cause them to be mistaken for cockroaches. Although, like some cockroaches, earwigs have wings, they fly very badly. Earwigs spread largely by infested plant material, cut flowers, and other human activities.

Earwig Problems

The earwigs' habit of hiding leads them into trouble with people. They often come indoors to hide, or they conceal themselves under outdoor furniture, hoses, garbage cans, or poor-fitting well caps. They do not breed indoors but simply hide, then become active at night.

Well Problems

Loose-fitting well caps provide an ideal hiding place for earwigs: dark and damp during the day. Once inside a well cap, an earwig may fall into the water, die, and decay, thereby increasing bacterial contamination of the well. Earwigs are not considered a public health threat and are not associated with any disease; nevertheless, you should replace poor-fitting well caps with vermin-proof caps to prevent any insects from contaminating the water.

Plant Damage

Earwigs eat small holes in plant leaves during the night. Earwig damage often appears small compared to the large pest populations present, and it can be confused with injuries caused by slugs, cutworms, or even rabbits. Larger plants will tolerate the feeding, but seedlings and flowering plants can be severely damaged or killed by dense populations.

You should suspect earwig problems if you find damage during the day but can't find any insects on the plants. Confirm the presence of earwigs by checking the plants at night, or by looking for them congregated under boards, firewood, or tree bark next to your plants.

Control

Earwigs congregate in areas that are shaded or filled with lush plant material, boards, debris, or organic mulch. Exposed, sunny yards have fewer problems. Two species of parasitic fly, including *Digonichaeta setipennis*, have been introduced to help control earwigs naturally. In good years these parasites attack and kill over ½ of the earwig population.

You can trap earwigs in rolled up newspapers or in old tuna fish cans baited with fish oil or vegetable oil. Place traps near the problem areas and check them each morning.

Please see EARWIGS, Page 5

Wisconsin Entomological Society Newsletter - November 1999

EARWIGS, from Page 4

Shake live insects into a pail of soapy water to kill them. Converting the backyard to a dry, sunny environment with few hiding places will also help control earwigs. Remove any shelter sites, prune lowgrowing bushes, avoid growing the earwigs' favored food plants, and destroy moss and algae. Avoid overwatering and don't use thick organic mulches.

Chemical

A variety of insecticides available to homeowners are labeled for earwig control. You can use the following materials as baits, liquid sprays, granules, or dust: diazinon, carbarvl (Sevin), chlorpyrifos (Dursban), and propoxur (Baygon). Read the label to determine the proper sites and vegetable restrictions. Applying insecticides to the daytime hiding places will give more successful control. Insecticide applications made late in the day are most effective. Wettable powders and granular formulations perform better. A common recommendation is to apply insecticides as a barrier treatment. Sprays or dust are applied to the exterior foundation walls and a 2-3 foot swath along the adjacent ground. Flower beds and mulches can also be treated. Many lawn insecticides could be used on grass, but that would be an extreme response to this problem.

Indoor

If earwigs are getting into your home, caulk cracks and crevices and weather-strip doors to prevent their entry. Check windows, the junction of the siding with the foundation, and all outdoor water faucets for openings that earwigs can squeeze through. Remove firewood, unneeded plant material, and organic mulches from the foundation area. Create a clean, dry border along the foundation and consider replacing wood chips or bark mulch with stones or other material that will be less attractive to earwigs. Clear debris and leaves from the troughs of eaves. V

Phil is president of WES and District Outreach Specialist at the Insect Diagnostic Lab, U. W. Madison, Dept. of Entomology.

Swallowtail Tale... A Summer Play in Three Acts by Pat Seawell

Act I

Few things are as rewarding as sharing nature's wonders with children. With that thought in mind. I planted Trailing Lantana Philip: "Mrs. Seawell, Avenger between the sidewalk and the curb in front of my San Antonio home.

Husband: "Pat-teeee, what's going on in our front yard? Every time I look out, there are kids I've never seen before squatting around that plant!"

Me: "Mmmmm, word travels fast Theo's mom: "Pat, guess what? in this neighborhood! My lab project is working even better than I thought it would! This morning I showed the Eastern few minutes it flew away. It was Black Swallowtail eggs to my ten- so exciting! Thank you for doing year-old neighbor, Theo. By evening, every child in the neighborhood has been by to peer at them."

Because of previous experiences with wasps, assassin bugs, anoles, and fire ants, I make a "protective Ding-dong! custody cage" for Theo's baby caterpillar. I showed him how to keep the Parsley fresh. He sets up his project on his living room coffee table. Seven-year-old Philip wants a pet. His nine-year-old Husband (in an aside to me): sister, Amy, wants a pet. They bring their mom over. We discuss the responsibilities involved in raising a pet caterpillar.

Me: "No, you won't have to make emergency trips to the supermarket like I did last year. I've planted enough parsley for the whole neighborhood." I make another protective custody cage. Me: Philip and Amy are ecstatic.

Ding-dong!

and Parsley in the narrow space has eaten almost all the parsley you gave me yesterday, may I have some more, please?"

Ding-dong!

Amy: "Mrs. Seawell, guess what? Watercolor has made a chrysalis!"

Ding-dong!

Theo's butterfly came out of the chrusalis this morning! We put it on a bush like you said and in a this! We're all enjoying it!"

Ding-dong!

Philip & Amy's dad: "We appreciate what you're doing for our children. They're learning so much. We never thought to do anything like this. Actually, Katherine and I are learning a lot, also!"

Theo's dad: "Theo and Philip both had butterflies this morning! We had a double launch! And I got it all on video!"

"When is this project scheduled to end?"

Me: "I thought they'd be bored with it after the first caterpillar."

Husband: "How many launches have YOU had so far this summer? Twenty-six? Twentyeight?"

"Mmmmm, I suppose I'd better plant some more parsley!"

Pat is a WES member residing in San Antonio, TX. By planting native shrubs and grasses, she is attracting an astonishing variety of moths and butterflies to the "wilderness" of her suburban backyard. A retired high school English teacher, she reads, writes books for children, and watches caterpillars graze.

Wisconsin Entomological Society Newsletter — November 1999

here is no better place I know to find Hummingbird Moths (*Hermaris thysbe*) than a severalacre tall-grass prairie remnant in Racine County. There, Hummingbird Moths are often seen nectaring on Field Thistle and Blazing Stars and their favorite flower, Wild Bergamot. On the last weekend in July 1997, when the bergamot was in peak bloom, I headed out to see the moths.

The largest clump of Wild Bergamot on this prairie measures about four by five feet. For many years, I have watched day-flying Hummingbird Moths nectar on this plant between the hours of 11:00 A.M. and 4:00 P.M. Today, just before noon, two moths, flashing iridescent green in the summer sun, fly past me and begin to nectar on the flowers. As approach, one of them flies off. The other remains, hovering over flower spurs, sipping nectar.

A spider web, connecting the undersides of two heads

of the tubular lavender flowers, catches my eye. In a corner of the web, not two inches in from the flowers, a large Cross Spider (Araneus diadematus) waits. As the moth nectars above, gettting closer to the flower above the spider's web, the spider moves towards the moth. At the outermost tubular flower, the moth hovers within two inches of the spider. In a flash, the moth drops-the large spider appears to have jumped out and grabbed it. In a fraction of a second, the spider is back on its web, wrapping the moth in spirals of silk.

As usual, I've forgotten a camera. But I have brought my sketchbook and I quickly sketch the spider at work. Several days later, while looking at my sketch and reading over my field notes, I start to think about what I've seen. An orbweaving spider, like the Cross Spider, responds only to vibrations on its web. The moth was not on the spider's web. How, then, did the spider catch its prey? I call Joan Jass at the Milwaukee Public Museum and explain what I've seen. Joan confirms that orb-weaving spiders cannot find prey unless it is touching their web. She asks me what I think happened.

Me? I'm neither spider nor moth expert, I'm merely an observer. But I

Sketch: Babette Kis

describe what I have seen and Joan and I come up with this possible explanation. Although the wings of a flying moth give off appetizing vibrations to a spider, an orbweaving spider only responds to these vibrations when they are transmitted through its web. To the best of my recollection, the moth was not touching the spider's web when it was caught. However, one of the moth's legs could have brushed the web, triggering the spider's response.

It may have been this way, but the moth showed no distress or erratic flight prior to being caught. Is there a way that the spider could have caught the moth if the moth didn't touch its web? With Joan's encouragement, I go through what I have seen again, this time focusing on how the vibrations of the moth could have been transmitted to the web without the moth actually touching the web. The spider's web was intertwined between flowers the moth nectared on just before it was caught. While the moth nectared, the vibrations from its wings were carried through its proboscis, into the nectar in the flower. The vibrations passed through the walls of the flower to the web. Could the spider have felt the direction and intensity of the vibrations through the web? Feeling these vibrations,

could the spider then have reached out and grabbed the moth as it hovered within a fraction of an inch of its web?

The whole episode of a spider "jumping out" to catch a moth seems somehow familiar to me. I pester my ever-patient husband to drag boxes of my old field notes out of the attic. After many evenings of reading through them, I find this old journal entry:

"Sunny, about 80, no wind. A few cumulus clouds. Saw four Hummingbird and three Bumblebee Moths. There is a European (Cross) Spider in a web under the wild pink mints (Wild Bergamot). I was very

close, and a Hummingbird Moth came and sipped nectar just over the spider. The spider jumped out and caught the moth. I hit the spider's web. The moth fell to the ground, then it flew off. How did it (the spider) know about the moth being there? How can a European spider catch a flying moth? I never saw these spiders catch anything that didn't get caught in its (their) web until now." — August 1963

Where did I make my August 1963 childhood observation? At the same place I saw the Cross Spider catch the Hummingbird Moth in July 1997. ♥

Babette is a wife and mother of three children, full-time project architect at the City of Milwaukee, part-time naturalist, writer, artist, and former science teacher. She has written notes and made sketches of her field observations from the time she was eight years old.
